## Thermodynamics

Chapter 4 Reversible Processes (Non-Flow \& Steady Flow) Irreversible Processes
Non-Steady Flow Process
Dr. Sajid Hussein Alabbasi
Department of Mechanical Engineering
Engineering College - University of Basrah

## Reversible Process

The reversible process is the ideal process which never occurs, while the irreversible process is the natural process that is commonly found in nature. When we tear a page from our notebooks, we cannot change this and 'un-tear'. This is an irreversible process. Whereas when water evaporates, it can also be condensed in the form of rains. This is a reversible process. Let us study more about them below.

A thermodynamic process is reversible if the process can return back in such a that both the system and the surroundings return to their original states, with no other change anywhere else in the universe. It means both system and surroundings are returned to their initial states at the end of the reverse process.

In the figure above, the system has undergone a change from state 1 to state 2 . The reversible process can reverse completely and there is no trace left to show that the system had undergone thermodynamic change. During the reversible process, all the changes in state that occur in the system are in thermodynamic equilibrium with each other.

- Dissipative force must be absent.
- The process should occur in infinite small time.

In simple words, the process which can reverse back completely is a reversible process. This means that the final properties of the system can perfectly reverse back to the original properties. The process can be perfectly reversible only if the changes in the process are infinitesimally small. In practical situations it is not possible to trace these extremely small changes in extremely small time, hence the reversible process is also an ideal process. The changes that occur during the reversible process are in equilibrium with each other, friction effects can be assumed to be negligible and heat must never be transferred to or from the system through a finite temperature difference .

## Non-Flow Reversible Processes :

## (Heating/Cooling and Expansion/Compression of Gases)

Until now we have studied that thermodynamic system of a gas is used to convert heat energy into work energy or vice versa which is required in a number of practical applications.

Thermodynamic system is also of many types. Here we will study a closed system which can exchange energy with surroundings but not the mass. Thus mass does not flow in or out of the system and so the processes of heating/cooling/compression/expansion etc are undergone by this fix mass of gas confined in continuous closed boundary are called Non-flow processes. In these processes some property of the gas may change and some may not change based on which a particular process is characterized. By applying first law of thermodynamics, the various forms of energy exchange can be calculated considering the processes as reversible i.e. taking all internal/external losses due to friction etc as nil.

For this let us consider a fix quantity of an ideal gas filled in a metallic cylinder as shown in below figure, one side of which is covered or fixed by a solid end plate and other side is covered by a moving piston. The outer wall of piston matches with inner wall of cylinder such that it makes a leak proof sliding joint. This moving piston makes one of the boundaries of system as moving or flexible.

Fig. Closed system of gas filled in metallic cylinder

When infinitely small heat $\delta Q$ is supplied to gas from outside through the wall of cylinder, the gas tends to expand and forces the piston weight F to move up. Let piston moves by a short distance, $d l$. Then the infinitesimal work done can be calculated as

$$
\begin{aligned}
& \delta \mathrm{W}=\mathrm{F} \times \mathrm{dl} \\
& =\frac{\mathrm{F}}{\mathrm{~A}} \times \mathrm{dl} \times \mathrm{A} \\
& \quad=\mathrm{P} . \mathrm{dV}
\end{aligned}
$$

## Work $=$ Pressure x Change in volume

Total work during a non-flow process 1-2 i.e. compression or expansion of gases can be calculated as taking integral of P.dV

$$
W=\int_{1}^{2} P \cdot d V
$$

Thus, first law of thermodynamics can be written as :

$$
\delta \mathrm{Q}=\mathrm{P} \cdot \mathrm{dV}+d U
$$

All these reversible processes of heat exchange (Heating or Cooling) and work exchange (compression or expansion) by a system of ideal gas with its surroundings can take place in various ways as discussed below:

1. Constant volume ( Isochoric ) heating/cooling process

Let the piston is fixed at one point in the walls of cylinder such that volume $\mathrm{V}=$ Constant
So the ideal gas law $\mathrm{PV} / \mathrm{T}=$ Constant will reduce to

$$
\frac{\mathrm{P}}{\mathrm{~T}}=\text { Constant }
$$

Now let a small increment of heat $\boldsymbol{\delta} \mathrm{Q}$ is supplied to the gas. According to the $1^{\text {st }}$ law of thermodynamics,

$$
\begin{aligned}
& \delta Q=\delta W+d U \\
& \delta Q=P \cdot d V+d U
\end{aligned}
$$

As $\mathrm{V}=$ Constant, $\boldsymbol{\delta} \mathrm{W}=\mathrm{P} . d V=0$, then the equation was written
For any work substance ( fluid )

$$
\mathbf{Q}=\Delta \mathbf{U}
$$

And for perfect gas, the equation can be written as :

$$
\text { So } \quad \delta Q=\Delta U=m C_{v} \Delta T
$$

Thus knowing the values of $\boldsymbol{\delta Q}$ and $\mathrm{C}_{\mathrm{v}}, \Delta T$ (Increase in temperature) can be calculated and so $\Delta P$ can also be calculated from eq.

$$
\frac{P}{T}=\text { Constant }
$$

By measuring the small increment in temperature and pressure of system, the quantity $\boldsymbol{\delta} \mathrm{Q} \& \Delta U$ can also be calculated.

## 2. Constant pressure ( Isobaric ) process

Let the piston is free to move in the cylinder and force, F or pressure, P on the piston remains constant. So now the boundaries of the system can move and so the gas can expand or can be compressed i.e. the system is able to exchange work.

Now let a small quantity of heat, $\boldsymbol{\delta} \mathbf{Q}$ is supplied to the gas through the walls of cylinder.
On absorbing this heat, the temperature of gas will tend to increase and simultaneously the gas will tend to expand against force F on the piston. Applying $1^{\text {st }}$ law of thermodynamic to this process.

$$
\begin{gathered}
\delta Q=\delta W+d U \\
O r \quad \delta Q=P \cdot d V+m C_{v} d T \\
\mathbf{Q}=\mathbf{P}\left(\mathbf{V}_{\mathbf{2}}-\mathbf{V}_{\mathbf{1}}\right)+\left(\mathbf{U}_{\mathbf{2}}-\mathbf{U}_{\mathbf{1}}\right) \\
\mathbf{Q}=\left(\mathbf{U}_{\mathbf{2}}+\mathbf{P} \mathbf{V}_{\mathbf{2}}\right)-\left(\mathbf{U}_{\mathbf{1}}+\mathbf{P} \mathbf{V}_{\mathbf{1}}\right)
\end{gathered}
$$

And for perfect gas, the equation can be written as :

$$
\begin{gathered}
\mathbf{Q}=\mathbf{C P}_{\mathbf{P}} \mathbf{\mathbf { T } _ { 2 }}-\mathbf{C P}_{\mathbf{P}} \mathbf{1} \\
\mathbf{Q}=\mathbf{C P}_{\mathbf{P}}\left(\mathbf{T}_{\mathbf{2}}-\mathbf{T}_{\mathbf{1}}\right) \\
\mathbf{Q}=\mathbf{C P}_{\mathbf{P}} \Delta \mathbf{T}=\mathbf{C P} \mathbf{d T} \\
Q=P\left(V_{2}-V_{1}\right)+m C_{v}\left(T_{2}-T_{1}\right)
\end{gathered}
$$

Also, work can be calculated for a perfect gas by equation :

$$
\mathrm{W}=\mathrm{P}\left(\mathrm{~V}_{2}-\mathrm{V}_{1}\right)=\mathrm{PV}_{2}-\mathrm{PV}_{1}=\mathrm{m} \mathrm{RT}_{2}-\mathrm{mRT}_{1}=\mathrm{mR}\left(\mathrm{~T}_{2}-\mathrm{T}_{1}\right)=\mathrm{m} \int \mathrm{RdT}
$$

Thus the increase in volume of gas due to expansion and increase in temperature are interrelated and if one can be measured the other can be found and the quantities $\mathrm{W}, \Delta \mathrm{U}$ and so Q can be calculated from equation as By ideal gas law
As pressure, $\mathrm{P}=\mathrm{Constant}$, the gas law reduce to $\mathrm{V} / \mathrm{T}=\mathrm{Constant}$

$$
\frac{P V}{T}=\text { Constant }=m R
$$

And the fist law of thermodynamics

$$
\begin{aligned}
& \quad \delta Q=\delta W+d U \\
& \delta Q=P \cdot d V+m C_{v} d T \\
& \text { or } \quad m C_{p} d T=m R d T+m C_{v} d T \quad\left[\because \frac{P \cdot d V}{d T}=m R\right]
\end{aligned}
$$

$$
\begin{array}{cc}
\text { or } & C_{p}=R+C_{v} \\
\text { or } & C_{p}-C_{v}=R
\end{array}
$$

Thus characteristic gas constant of an ideal gas is the difference between specific heat at constant pressure $\left(\mathrm{C}_{\mathrm{p}}\right)$ and at constant volume ( $\mathrm{C}_{\mathrm{v}}$ ).

The ratio of specific heats $\mathbf{C}_{\mathbf{p}} / \mathbf{C}_{\mathbf{v}}$ is denoted as $\boldsymbol{\gamma}$.
The physical meaning of R or $\gamma$ can be taken as the characteristic of an ideal gas to expand under the influence of heat or we can say the increase in product of pressure and volume PV with increase in T .

## 3. Constant temperature ( Isothermal ) Process

## a. Steam

It can seen, that the isothermal process for a wet steam lay at the constant pressure line also. Thus the heat calculated by equation :

$$
\mathbf{Q}=\mathbf{H}_{\mathbf{2}}-\mathbf{H}_{\mathbf{1}}
$$

or

$$
\mathbf{Q}=\mathbf{U}_{2}-\mathbf{U}_{1}+\mathbf{W}
$$

## b. Ideal gas ( perfect gas )

V

The beauty of isothermal expansion or compression process ( when the working substance is ideal gas ) is that the internal energy remains constant and so whole of the heat exchange by system is converted to work and vice versa. However the process is difficult to visualize while thinking that when the system (gas filled behind piston in the cylinder) absorbs heat, its temperature should always increase. But what happens in the isothermal process that while absorbing heat, simultaneously the gas expands thus decrease in its pressure and temperature takes place and the net change in temperature is zero. While expanding, the gas gives positive work equal to the heat supplied. Conversely also if the gas is compressed by doing extra work on the gas, its pressure and temperature tends to increase, but simultaneously if the gas is cooled in such proportion that the net change in temperature remains zero, the compression process becomes isothermal. In this isothermal compression process, again the work supplied to the gas is given away by the system in the form of heat. Applying first law of thermodynamics to this isothermal process in which

$$
\begin{gathered}
\boldsymbol{d} \boldsymbol{u}=\mathbf{0}, \text { because } \boldsymbol{d} \boldsymbol{t}=\mathbf{0} \\
\boldsymbol{\delta} \mathrm{Q}=\boldsymbol{\delta} \mathrm{W}=\mathrm{P} \cdot d V \\
Q=W=\int_{1}^{2} P \cdot d V
\end{gathered}
$$

From ideal gas law

At $\mathrm{T}=$ constant
Gas law reduces to $\mathrm{PV}=$ constant or

$$
\frac{\mathrm{PV}}{\mathrm{~T}}=\text { constant }
$$

$$
\mathrm{P}_{1} \mathrm{~V}_{1}=\mathrm{P}_{2} \mathrm{~V}_{2}=\mathrm{PV}
$$

Putting this in equation

$$
Q=W=\int_{1}^{2} \frac{P_{1} V_{1}}{V} \cdot d V=P_{1} V_{1} \int_{1}^{2} \frac{d V}{V}
$$

## $\mathbf{Q}=\mathbf{W}=\mathbf{P}_{\mathbf{1}} \mathbf{V}_{\mathbf{1}} \ln \frac{v_{2}}{v_{1}}$

By using this equation we can calculate the work exchange or heat exchange during isothermal process if we know the change in volume.

Also in case of Isothermal process we know that

$$
\begin{gathered}
\mathrm{P}_{1} \mathrm{~V}_{1}=\mathrm{P}_{2} \mathrm{~V}_{2} \\
\frac{V_{2}}{V_{1}}=\frac{P_{1}}{P_{2}}
\end{gathered}
$$

Putting in eq.

By using this equation, we can calculate the work exchange or heat exchange if we know the change in pressure.

- The system does not exchange heat with the surrounding
- System is completely insulated from surrounding
From non - flow equation ( first law of thermodynamics )

$$
\begin{gathered}
\mathbf{Q}=\mathbf{U}_{2}-\mathbf{U}_{1}+\mathbf{W} \\
\mathbf{Q}=\mathbf{0}
\end{gathered}
$$

Thus, for any adiabatic process whether it is reversible or not, and for a vapour undergoing a reversible adiabatic process the work done can be found by :

$$
\mathbf{U}_{1}-\mathbf{U}_{2}=\mathbf{W}
$$

And for an ideal gas, where $\mathrm{Q}=0$, The non flow equation is :

$$
\begin{gathered}
d q=d u+d w=0 \\
d q=d u+p d v=0 \\
d u+p d v=0 \\
P V=R T
\end{gathered}
$$

For unit mass

$$
\begin{gathered}
\mathrm{P}=\frac{\mathrm{RT}}{\mathrm{~V}} \\
\mathrm{du}+\frac{\mathrm{RT} d V}{\mathrm{~V}}=0 \\
\mathrm{C}_{\mathrm{V}} \mathrm{dT}+\frac{\mathrm{RT} d V}{\mathrm{~V}}=\mathbf{0} \\
\mathrm{C}_{\mathrm{v}} \frac{d T}{\mathrm{~T}}+\mathrm{R} \frac{d V}{\mathrm{~V}}=0
\end{gathered}
$$

## $C_{v} \operatorname{LnT}+\mathrm{RLn} \mathrm{V}=$ Constant

Where $T=\frac{P V}{R}$
$\left[\operatorname{Cv} \operatorname{Ln} \frac{P V}{R}+\mathbf{R L n} \mathbf{V}=\mathbf{C o n s t a n t}\right]$ divided by $C_{V}$

$$
\operatorname{Ln} \frac{\mathrm{P} \mathrm{~V}}{\mathrm{R}}+\frac{\mathrm{R}}{C v} \operatorname{Ln} \mathbf{V}=\mathbf{C o n s t a n t}
$$

Where $\mathrm{Cv}=\frac{\mathrm{R}}{\gamma-1} \quad, \quad r-1=\frac{\mathrm{R}}{C v}$

$$
\begin{gathered}
\operatorname{Ln} \frac{P V}{R}+(\gamma-1) \operatorname{Ln} \mathbf{V}=\text { Constant } \\
\operatorname{Ln} \frac{P V}{R}+\operatorname{Ln} V^{(r-1)}=\text { Constant }
\end{gathered}
$$

$$
\mathbf{L n} \frac{P V^{\Upsilon}}{R}=\text { Constant } \quad \text { Then } \quad \frac{P V^{\Upsilon}}{R}=e^{\text {constant }}
$$

$$
\mathbf{P V}^{r}=\text { Constant }
$$

Thus perfect gas expand / compress according to the equation :

$$
\mathbf{P V}^{\gamma}=\text { Constant }
$$

$$
\mathbf{P}=\frac{\mathbf{C}}{\mathrm{v}^{⿹}}
$$

Then the work found by :

$$
\begin{gathered}
\mathbf{W}=\mathbf{U}_{1}-\mathbf{U}_{2}=\int^{2} \mathrm{P} \mathbf{d V} \\
\mathbf{W}=\mathbf{C}_{\mathbf{V}} \mathbf{d T}=\mathbf{C}_{\mathbf{V}}\left(\mathbf{T}_{2}-\mathbf{T}_{1}\right) \\
\mathbf{W}={ }_{1} \int^{2} \frac{\mathbf{C}}{\mathbf{V}^{\gamma}} \mathbf{d V}=\mathbf{C} \int_{1}^{2} \frac{\mathbf{d V}}{\mathbf{V}^{\gamma}} \\
\text { or } \mathbf{W}=\mathbf{C}\left[\frac{\mathbf{V}^{1-\gamma}}{1-\gamma}\right]_{1}^{2}=\mathbf{P V}^{\gamma}\left[\frac{\mathbf{V}^{1-\gamma}}{1-\gamma}\right]_{1}^{2}=\frac{\mathbf{P}_{2} \mathbf{V}_{2}-\mathbf{P}_{1} \mathbf{V}_{1}}{1-\gamma} \\
\mathbf{W}=\frac{\mathbf{P}_{1} \mathbf{V}_{1}-\mathbf{P}_{2} \mathbf{V}_{2}}{\gamma-1}
\end{gathered}
$$

By equations $\mathbf{P V}^{\boldsymbol{r}}=\mathbf{C o n s t a n t , ~ a n d ~} \frac{\mathbf{P V}}{\mathbf{T}}=$ Constant, can found

$$
\begin{aligned}
& \mathbf{T}_{2}=\mathbf{T}_{1}\left(\frac{\mathbf{V}_{1}}{\mathbf{V}_{2}}\right)^{\gamma-1} \\
& \mathbf{T}_{2}=\mathbf{T}_{1}\left(\frac{\mathbf{P}_{2}}{\mathbf{P}_{1}}\right)^{(\gamma-1) / \gamma}
\end{aligned}
$$

## 5. Polytropic Process

It is found that many processes in practice approximate to reversible law of the form $\mathbf{P V}^{\mathbf{n}}=\mathbf{C o n s t a n t}$, where n is
a constant. The index n depends only on the heat and work quantities during the process . Both vapours and perfect gases obey this type of closely in many non-flow processes. Such processes are internally reversible. Thus perfect gas expand / compress according to the law :

$$
P V^{n}=\text { Constant, } \quad \text { then } P=\frac{c}{V^{n}}
$$

Then the work found by :

$$
\begin{aligned}
& W=\int^{2} \mathrm{PdV} \\
& W=\int^{2} \frac{C}{V^{n}} d V=C \quad \int^{2} \frac{d V}{V^{n}} \\
& \mathbf{W}=\mathbf{C}\left[\frac{\mathbf{V}^{1-n}}{1-n}\right]_{1}^{2}=\mathbf{P V}^{\mathrm{n}}\left[\frac{\mathbf{V}^{1-n}}{1-n}\right]_{1}^{2}=\frac{\mathbf{P}_{2} \mathbf{V}_{2}-\mathbf{P}_{1} \mathbf{V}_{1}}{1-n} \\
& W=\frac{P_{1} V_{1}-P_{2} V_{2}}{n-1} \\
& \mathrm{~T}_{\mathbf{2}}=\mathrm{T}_{1}\left(\frac{\mathbf{V}_{1}}{\mathbf{V}_{\mathbf{2}}}\right)^{\mathrm{n}-\mathbf{1}} \\
& \mathbf{T}_{2}=\mathbf{T}_{1}\left(\frac{\mathbf{P}_{2}}{\mathbf{P}_{1}}\right)^{(\mathbf{n}-\mathbf{1}) / \mathbf{n}}
\end{aligned}
$$

By equations $\mathbf{P V}^{\mathbf{n}}=$ Constant, and $\frac{\mathbf{P V}}{\mathbf{T}}=$ Constant, can found

$$
\mathbf{W}=\frac{\mathbf{P}_{1} V_{1}-P_{2} V_{2}}{n-1}
$$

$$
w=\frac{R\left(T_{1}-T_{2}\right)}{n-1}
$$

While the total work is

$$
\mathrm{W}=\frac{\mathrm{mR}\left(\mathrm{~T}_{1}-\mathrm{T}_{2}\right)}{n-1}
$$

$$
\mathbf{Q}=\mathbf{U} 2-\mathbf{U} 1+\mathbf{W}=\mathbf{C v}\left(\mathrm{T}_{1}-\mathrm{T}_{2}\right)+\frac{\mathrm{R}\left(\mathrm{~T}_{1}-\mathrm{T}_{2}\right)}{n-1}
$$

Where $\mathbf{C v}=\frac{\mathrm{R}}{\gamma-1}$,

$$
\begin{aligned}
& Q=\frac{R\left(T_{1}-T_{2}\right)}{n-1}-\frac{R}{\gamma-1}\left(T_{1}-T_{2}\right) \\
& Q=R\left(T_{1}-T_{2}\right)\left[\frac{1}{n-1}-\frac{1}{\gamma-1}\right]
\end{aligned}
$$

$$
\mathbf{Q}=\left[\frac{\gamma-n}{\gamma-1}\right] \frac{\mathbf{R}\left(\mathbf{T}_{1}-\mathbf{T}_{2}\right)}{n-1}=\left[\frac{\gamma-n}{\gamma-1}\right] \mathbf{W}
$$

## There are 2-types of specific heats: <br> 1. Specific Heat at Constant Volume $\mathbf{C}_{\mathrm{v}}$

It is the amount of heat required to rise the temperature of unit mass of a gas through one degree when the volume is constant.
If a unit mass of a gas is taken in a closed vessel and is heated, the volume of the gas remains constant, but the temperature
increases. As the volume remains constant, there is no external work done by the gas and as temperature of the gas increases, there is increase in internal energy of the gas.
Therefore heat supplied to the gas is completely utilized in increasing the I.E. of the gas,
2. Specific Heat at Constant Pressure $C_{p}$ :

It is the amount of heat required to rise the temperature of unit mass of a gas through one degree when the pressure is kept constant.
Consider a unit mass of a gas in a cylinder fitted with a frictionless piston. When the gas is heated, the piston moves up, maintaining the same pressure. But the volume and temperature of the gas increases during heating.
As there is increase in volume, there is external work done by the gas and there is increase in temperature, there is increase in I.E.

Thus heat supplied when the pressure is constant, is utilized for two purposes:
(a) To do some external work.
(b) To increase the I.E of the gas.

Whereas in case of constant volume heating, the heat supplied is completely utilized for increasing the I.E.
$\therefore$ Specific heat at constant pressure is greater than specific heat at constant volume.
i.e.,

$$
\begin{aligned}
C_{P} & >C_{V} \\
C_{P} & =\left[\frac{d h}{d T}\right]_{P}
\end{aligned}
$$

and,

$$
C_{P}=\left[\frac{\delta q}{d T}\right]_{P}
$$

Also

Therefore, $\mathrm{C}_{\mathrm{p}}$ is also defined as, the rate of change of specific enthalpy with respect to temperature when the pressure is kept constant.
6. Adiabatic Index:

It is the ratio of specific heat at constant pressure to the specific heat at constant volume and is given by,

$$
\begin{gathered}
K \text { or } \gamma=\frac{C_{p}}{C_{v}} \\
\text { Note: For air, } C_{p}=1.005 \frac{\mathrm{~kJ}}{\mathrm{~kg}-\mathrm{K}} \text { and } C_{v}=0.718 \frac{\mathrm{~kJ}}{\mathrm{~kg}-\mathrm{K}} \text { and } \gamma=1.4
\end{gathered}
$$

## Internal Energy of an Ideal Gas

We will show that the internal energy of an ideal gas is a function of temperature only. This makes physical sense because there is an assumption in ideal gas behavior that there is no interaction between the molecules when we write
Start with a reversible process for an ideal gas:

$$
\begin{aligned}
& P \bar{V}=R T \\
& d U=d q+d w=d q-P d V
\end{aligned}
$$

Consider two processes: one occurring at constant volume, the other occurring at constant pressure.

Figure : Two consecutive processes, constant volume followed by constant pressure.

For process 1: At constant $V(P d V=0)$

## 18

$$
d U=C_{V} d T+0
$$

i.e $U$ is $f(T)$ only

$$
\mathrm{dU}=\mathrm{C}_{\mathrm{v}} \mathrm{dT}
$$

This can be integrated because $T$ is the only thing that is changing on the right hand side ( $\mathrm{C}_{\mathrm{v}}$ is assumed to be independent of $T$ and $V$ ).

For process 2:

$$
d U=C_{P} d T-P d V
$$

P is constant (i.e., not a function of $T$ or $V$ ) so it can be integrated directly. Using the iqleal gas law:

$$
\mathrm{PV}=\mathrm{nRT}
$$

For one mole of gas (i.e $n=1$ )

$$
\mathrm{PdV}+\mathrm{VdP}=\mathrm{RdT}
$$

At constant $\mathrm{P}(\mathrm{VdP}=0)$

$$
\mathrm{PdV}=\mathrm{RdT}
$$

Then

$$
\mathbf{d U}=\mathbf{C}_{\mathbf{p}} \mathbf{d T}-\mathbf{R d T}
$$

So

$$
\mathbf{d U}=\left(\mathbf{C}_{\mathbf{p}}-\mathbf{R}\right) \mathbf{d T}
$$

$$
C_{v}=C_{p}-\mathbf{R}
$$

Then $\mathbf{d U}=\mathbf{C}_{\mathbf{v}} \mathbf{d T}$ or

$$
\mathbf{d U}=\mathrm{C}_{\mathrm{v}} \mathbf{d T} \quad \text { or }
$$

$$
\mathrm{dU}=\frac{C p}{\gamma} \mathrm{dT}
$$

, $\mathbf{U}$ is $\mathbf{f}(\mathbf{T})$ only.
Note: that $\mathrm{\gamma}=\frac{\boldsymbol{c p}}{\boldsymbol{c} \boldsymbol{v}}$

$$
C_{v}=\frac{R}{\gamma-1} \quad \text { and } \quad C_{p}=\frac{\gamma R}{\gamma-1}
$$

## Summary

A perfect gases obey this type of closely in many non-flow processes. Such processes are internally reversible according to the law : $\quad \mathbf{P V}$ index $=$ Constant. And $\frac{P V}{T}=$ Constant .

1. If index $=\infty$, the process is to be called Isochoric process i.e $\mathbf{V}=$ Constant $(\mathbf{P})^{(1 / \infty)}=$ Constant. If the gas is an ideal gas. Then, $\mathbf{P} / \mathrm{T}=$ Constant
2. If index $=1$, the process is to be called Isothermal process i.e $\mathbf{T}=$ Constant. Then, $\mathbf{P V}=$ Constant
3. If index $=0$, the process is to be called Isobaric process i.e $\mathbf{P}=$ Constant. Then $\frac{V}{T}=$ Constant .
4. If index $=\boldsymbol{r}$, the process is to be called adiabatic process. Then, $\mathrm{PV}^{\boldsymbol{r}}=$ Constant
5. If index $=\mathbf{n}$, the process is to be called polytropic process. Then, $\mathrm{PV}^{\mathrm{n}}=$ Constant

## Steasdy Flow Reversible Processes :

The energy balance for a steady-flow device (nozzle, compressor, turbine and pump) with one inlet and one exit is:

$$
\begin{aligned}
& K E_{1}+P E_{1}+I E_{1}+W E_{1}+Q=K E_{2}+P E_{2}+I E_{2}+W E_{2}+W \\
& \frac{C_{1}{ }^{2}}{2}+g Z_{1}+U_{1}+P_{1} V_{1}+Q=\frac{C_{2}{ }^{2}}{2}+g Z_{2}+U_{2}+P_{2} V_{2}+W \text { One-inlet-one-exit Nozzle } \\
& \frac{C_{1}{ }^{2}}{2}+g Z_{1}+H_{1}+Q=\frac{C_{1}{ }^{2}}{2}+g Z_{1}+H_{2}+W \\
& \mathbf{Q}-\mathbf{W}=\Delta \mathbf{H}+\Delta \mathbf{K} \mathbf{E}+\Delta \mathbf{P} \mathbf{E} \\
& \text { dq - dw }=\mathbf{d h}+\text { dke }+ \text { dpe }
\end{aligned}
$$

If the device undergoes an internally reversible process, the heat transfer term $\delta \mathrm{q}$ can be replaced by $\mathrm{dh}-\mathrm{vdP}$ since

$$
\begin{gathered}
h=u+p v \\
d h=d u+p d v+v d p \\
d h-v d p=d u+p d v \\
d q=d u+p d v \\
d q=d h-v d p
\end{gathered}
$$

Then the energy balance becomes

$$
d h-v d p-d w=d h+d k e+d p e
$$

By rearranging the above equation, the reversible steady-flow work can be expressed as

$$
-\mathbf{d w}_{\text {reversible }}=\mathrm{v} \text { dp + dke +dpe }
$$

Integrating it form location 1 to location 2 yields

$$
W_{\mathrm{rev}}=-\int_{1}^{2} v \mathrm{dP}-\Delta k e-\Delta p e
$$

The above equation is the relation for the reversible work output associated with an internally reversible process in a steady-flow device. When the changes in kinetic and potential energies are negligible, the relation reduces to

$$
\mathrm{w}_{\mathrm{rev}}=-\int_{1}^{2} \mathrm{vdP}
$$

The above equation states that the larger the specific volume, the larger the reversible work produced or consumed by a steady-flow device. To minimize the work input during a compression process, one should keep the specific volume of the working fluid as small as possible. In the same manner, to maximize the work output during an expansion process, one should keep the specific volume of the working fluid as large as possible.

One needs to know the relationship between the specific volume v and the pressure P for the given process to perform the integration in the above relation. If an incompressible fluid is used as the working fluid, the specific volume v is a constant. The relation for the reversible work output associated with an internally reversible process in a steady-flow device is simplified to give

$$
\mathbf{W}_{\text {rev. }}=-\mathbf{V}\left(\mathbf{P}_{2}-\mathbf{P}_{1}\right)-\text { dke }- \text { dpe }
$$

Hydraulic turbines used in hydroelectric power plants run in a steady-flow process with incompressible fluid, i.e., water, as the working fluid.

## Water Flowing through a Hydraulic Turbine

If no work interactions are involved, like nozzle or pipe section, the above equation is reduced to
where V is the velocity
or of the fluid. This equation is known as the Bernoulli

$$
v\left(P_{2}-F_{1}\right)+\frac{v_{2}^{2}-v_{1}^{2}}{2}+g\left(z_{2}-z_{1}\right)=0
$$

$$
\left(F_{2}-F_{1}\right)+\rho \frac{v_{2}^{2}-v_{1}^{2}}{2}+\rho g\left(z_{2}-z_{1}\right)=0
$$ equation in fluid mechanics.

## Reversible Steady - flow Devices produce Most and Consume Least Work

The steady-flow devices deliver the most and consume the least work when it undergoes a reversible process. 23 Consider two steady-flow devices, one is reversible and the other is irreversible (actual process), operating between the same inlet and exit states. The differential forms for the energy balance of these two devices are

$$
\begin{aligned}
& \delta q_{\mathrm{act}}-\delta \mathbf{w}_{\mathrm{act}}=\mathrm{dh}+\mathrm{dke}+\mathrm{dpe} \\
& \delta q_{\mathrm{rev}}-\delta \mathbf{w}_{\mathrm{rev}}=\mathrm{dh}+\mathrm{dke}+\mathrm{dpe}
\end{aligned}
$$

The right hand sides of these two equations are the same. It gives,

$$
\mathbf{q}_{\mathrm{act}}-\boldsymbol{\delta} \mathbf{w}_{\mathrm{act}}=\mathbf{q}_{\mathrm{rev}}-\boldsymbol{\delta} \mathbf{w}_{\mathrm{rev}}
$$

Rearranging this equation gives,

$$
\delta \mathbf{w}_{\mathrm{rev}}-\boldsymbol{\delta} \mathbf{w}_{\mathrm{act}}=\mathbf{q}_{\mathrm{rev}}-\mathbf{q}_{\mathrm{act}}
$$

Since $\mathbf{q}_{\text {rev }}=$ Tds, the above equation becomes,

$$
\delta \mathbf{w}_{\mathrm{rev}}-\delta \mathbf{w}_{\mathrm{act}}=\mathrm{Tds}-\mathbf{q}_{\mathrm{act}}
$$

the increase of entropy principle gives

$$
\mathrm{ds} \geq \frac{\delta \mathrm{q}_{\text {act }}}{\mathrm{T}}
$$

Thus,

$$
\boldsymbol{\delta} \mathbf{w}_{\text {rev }}-\boldsymbol{\delta} \mathbf{w}_{\text {act }} \geq 0 \quad \text { or } \quad \boldsymbol{\delta} \mathbf{w}_{\text {rev }} \geq \boldsymbol{\delta} \mathbf{w}_{\text {act }}
$$

Reversible Turbine Delivers more Work than Actual Turbine

That is, for the same inlet and exit conditions, when the device undergoes a reversible process, a work-produce device like turbine produces the most work ( w is positive), or a work-consuming device like compressor consumes the least work ( w is negative).

Some work is done on or by the gas by virtue of the forces acting between the moving gas and it's surrounding, us For reversible adiabatic flow process for a perfect gas, for the flow equation :

$$
\frac{C_{1}^{2}}{2}+g Z_{1}+H_{1}+Q=\frac{C_{1}^{2}}{2}+g Z_{1}+H_{2}+W
$$

Adiabatic means, $\mathbf{Q}=\mathbf{0}, \boldsymbol{\&}$ same elevation $\mathbf{Z}_{\mathbf{1}}=\mathbf{Z}_{\mathbf{2}}$

$$
W=\left(h_{1}-h_{2}\right)+\left(\frac{C_{1}{ }^{2}-C_{2}^{2}}{2}\right)
$$

## Irreversible Process

Irreversible processes are a result of straying away from the curve, therefore decreasing the amount of overall work done. An irreversible process is a thermodynamic process that departs from equilibrium. In terms of pressure and volume, it occurs when the pressure (or the volume) of a system changes dramatically and instantaneously that the volume (or the pressure) do not have the time to reach equilibrium.

Irreversible

A classic example of an irreversible process is allowing a certain volume of gas to release into a vacuum. By releasing pressure on a sample and allowing it to occupy a large space, the system and surroundings are not in equilibrium during the expansion process.

Here little work occurs. However, there is a requirement of significant work, with a corresponding amount of energy dissipation as heat flows to the environment. This is in order to reverse the process.

## Non-Flow Irreversible Processes :

## free expansion

Consider an ideal gas that is held in half of a thermally insulated container by a wall in the middle of the container. The other half of the container is under vacuum with no molecules inside. Now, if we remove the wall in the middle quickly, the gas expands and fills up the entire container immediately, as shown in (Figure).

A gas expanding from half of a container to the entire container (a) before and (b) after the wall in the middle is removed.

Because half of the container is under vacuum before the gas expands there, we do not expect any work to be

 done by the system that is, $\mathbf{W}=\mathbf{0}$ because no force from the vacuum is exerted on the gas during the expansion. If the container is thermally insulated from the rest of the environment, we do not expect any heat transfer to the system either, so $\mathbf{Q}=\mathbf{0}$. Then the first law of thermodynamics leads to the change of the internal energy of the system,

$$
\Delta \mathbf{U}=\mathbf{Q}-\mathbf{W}
$$

For an ideal gas, if the internal energy doesn't change, then the temperature stays the same i.e $\mathbf{T}_{1}=\mathbf{T}_{\mathbf{2}}$. Thus, the equation of state of the ideal gas gives us the final pressure of the gas,

$$
\mathbf{P} \mathbf{V}=\mathbf{n R T} \text { then } \mathbf{P V}=\mathbf{C o n s t a n t} \quad \text { i.e } \frac{P_{1}}{P_{2}}=\frac{V_{2}}{V_{1}}
$$

Where $\mathrm{P}_{\mathrm{O}}$ is the pressure of the gas before the expansion. The volume is doubled and the pressure is halved, but nothing else seems to have changed during the expansion.

Let us see another example of irreversibility in thermal processes. Consider two objects in thermal contact: one at temperature and the other at temperature $\mathrm{T}_{2}>\mathrm{T}_{1}$, as shown in (Figure)

Spontaneous heat flow from an object at higher temperature $T_{2}$ to another at lower temperature $T_{1}$. We know from common personal experience that heat flows from a hotter object to a colder one. For example, when we høld a few pieces of ice in our hands, we feel cold because heat has left our hands into the ice. The opposite is true when we hold one end of a metal rod while keeping the other end over a fire.

## Steady Flow Irreversible Processes :

## Throttling Process ( Isenthalpic Process )

A throttling process is a thermodynamics process, in which the enthalpy of the gas or medium remains constant ( $\mathbf{h}=\mathbf{c o n s t a n t}$ ). In fact, the throttling process is one of isenthalpic processes ( $\mathbf{S}=\mathbf{C o n s t a n t}$ ). During the throttling process no work is done by or on the system ( $\mathbf{d W}=\mathbf{0}$ ), and usually there is no heat transfer (adiabatic) from or into the system $(\mathbf{d Q}=\mathbf{0})$. On the other the throttling process cannot be isentropic, it is a fundamentally irreversible process. Characteristics of throttling process:

1. No Work Transfer
2. No Heat Transfer
3. Irreversible Process
4. Isenthalpic Process

Figure: Throttling Process by a Valve

partially open valve

porous plug

A throttling of the flow causes significant reduction in pressure, because a throttling device causes a local pressure loss. A throttling can be achieved simply by introducing a restriction into a line through which a gas or liquid flows. This restriction is commonly done by means of a partially open valve or a porous plug. Such pressure losses are generally termed minor losses, although they often account for a major portion of the head loss. The minor losses are roughly proportional to the square of the flow rate .

## Throttling devices

Floiw restriction

Capilfary tube expansion valve used to drop refrigerant pressure and temperature

$$
\min \left(h_{2}-h_{1}+\frac{T_{2}^{2}-T_{1}^{2}}{2}\right)=0
$$

Throttling is an isenthaipic process.

Fundamdentally,

$$
h_{2}=h_{1}
$$ non-quasiequilibrium.

## Non-Steady Flow Process

In the previous sections, it was noted that nozzles, diffusers, turbines, compressors and other devices undergo a steady flow process because of their long-time running consideration. But their start up and shutdown periods undergo transient operations since their states change with time. The flow processes involved are called unsteady-flow processes, or transient-flow processes. Unlike steady-flow processes, unsteady-flow processes start and end over some finite time period $(\Delta t)$. An additional example of an unsteady-flow process is filling or discharging a tank (internal energy as well as mass of the tank changes with time). Anther example is the condition of water in the cylinder jacket of an Internal Combustion engine (is time dependant).

In a steady flow process we have assumed that the mass and energy within the system remain constant and do not vary with time. In an unsteady flow process, mass and energy within the control volume vary continuously.

During an unsteady-flow process, the mass in the control volume changes with time. The mass balance for a system undergoing any process, can be used for control volume as

$$
\Sigma \mathbf{m}_{\mathrm{i}}-\Sigma \mathbf{m}_{\mathrm{e}}=\mathbf{m}_{2}-\mathbf{m}_{1}=\Delta \mathbf{m}_{\text {control volum }}
$$

$\mathrm{m}_{\mathrm{i}}=$ the mass flow into the control volume through one inlet $m_{e}=$ the mass flow out of the control volume through one exit $\mathrm{m}_{1}=$ the mass of the fluid in the control volume before process $\mathrm{m}_{2}=$ the mass of the fluid in of the control volume after process

Or in rate form ( mass per time $\frac{\mathbf{k g}}{\mathbf{s e c}}$ )

$$
\Sigma \mathrm{m}_{\mathrm{i}}^{\prime}-\Sigma \mathrm{m}_{\mathrm{e}}^{\prime}=\frac{\mathbf{d m}_{\mathrm{cv}}}{\mathrm{dt}}=\mathbf{d m ^ { \prime }}{ }_{\mathrm{Cv}}^{\prime}
$$

where
$\mathrm{m}_{\mathrm{i}}=$ the mass flow rate into the control volume through one inlet
$\mathrm{m}_{\mathrm{e}}^{\prime}=$ the mass flow rate out of the control volume through one exit
$\mathrm{dm}^{\prime}{ }_{\mathrm{CV}}=$ the rate of change of mass within the control volume
The energy can be transferred by heat, work, and mass only, the energy balance can be rewritten as :

$$
\delta Q+\delta m_{i}\left(K E_{i}+P E_{i}+I E_{i}+W E_{i}\right)-\delta W-\delta m_{e}\left(K E_{e}+P E_{e}+I E_{e}+W E_{e}\right)=\Delta I E_{C V}
$$

Where $\Delta \mathbf{I} \mathbf{E}_{\mathrm{cv}}=\mathbf{m}_{\mathbf{2}} \mathbf{U}_{\mathbf{2}}-\mathbf{m}_{\mathbf{1}} \mathbf{U}_{\mathbf{1}}$ is the change of internal energy of the system (control volume )

$$
\begin{gathered}
Q-W+\delta m_{i}\left(\frac{C_{i}^{2}}{2}+g z_{i}+u_{i}+p_{i} v_{i}\right)-\delta m_{e}\left(\frac{C_{e}{ }^{2}}{2}+g z_{e}+u_{e}+p_{e} v_{e}\right)=m_{2} u_{2}-m_{1} u_{1} \\
Q-W+\delta m_{i}\left(\frac{C_{i}^{2}}{2}+g z_{i}+h_{i}\right)-\delta m_{e}\left(\frac{C_{e}^{2}}{2}+g z_{e}+h_{e}\right)=\Delta U_{C V}
\end{gathered}
$$

Where $\Delta \mathrm{U}_{\mathrm{CV}}=\mathrm{U}_{\mathbf{2}}-\mathrm{U}_{\mathbf{1}}=\mathrm{m}_{2} \mathrm{u}_{2}-\mathrm{m}_{1} \mathrm{u}_{1}$

$$
\mathrm{h}=\mathrm{u}+\mathrm{p} \mathrm{v}
$$

Note that any term can be negligible depending on the application of device. For example of the non steady flow process is the case in which a vessel is opened to large space and fluid is allowed to escape. There is no work done and in this case $m_{i}=0$ since no mass enters the system, neglecting changes in potential energy and applying above equation :

$$
\mathbf{Q}-\delta \mathbf{m}_{e}\left(\frac{\mathbf{C}_{\mathrm{e}}^{2}}{2}+\mathbf{h}_{\mathrm{e}}\right)=\Delta \mathbf{U}_{\mathbf{C V}}
$$

When no mass is entering or leaving the control volume, and the kinetic and potential energy changes associated with the control volume are negligible, the energy equation can be reduced to the first law relation for

$$
\begin{aligned}
& \mathrm{m}_{2}=\mathrm{m}_{1}=\mathbf{m} \\
& Q-W=\sum m_{e}\left(\frac{h_{e}}{2}+g z_{e}\right) \\
& -\sum m_{i}\left(b_{i-}-\frac{v_{i}}{2}+g z_{i}\right)+ \\
& +\left[m_{2}(u+k e+p e)_{2}-m_{1}(u+k e+p e)_{1}\right] \\
& Q-W=m\left(L_{2}-L_{1}\right)
\end{aligned}
$$

System Reduces to a Closed System When all the Inlets and Exits are Closed
