## Fins

Extended bodies or fins are used to increase the rate of heat transfer by increasing the effective surface area or convective heat transfer. Fins are used in a large number of applications such as heat exchanger, cooling reactor core, electrical transformer and motors, automobile applications, rectifier, etc

Various types of simple-shaped fins, namely, rectangular, square, annular, cylindrical and tapered, have been used with different geometrical combinations.

Different types of finned surfaces. (a) Straight fin of rectangular profile on plane wall, (b) straight fin of rectangular profile on circular tube, (c) cylindrical tube with radial fin of rectangular profile, (d) cylindrical-spine or circular-rod fin.

(a)

(b)

(c)

(d)

For rectangular fin having a temperature $\mathrm{T}^{\circ}$ at the base surrounded by a fluid temperature $\mathrm{T} \infty$ Energy in left face = energy out right face + energy lost by convection.

Assuming steady state one dimensional without heat generation

The 3 energies terms are respectively:

$$
\begin{aligned}
\text { Energy in left face } & =q_{x}=-k A \frac{d T}{d x} \\
\text { Energy out right face } & \left.=q_{x+d x}=-k A \frac{d T}{d x}\right]_{x+d x} \\
& =-k A\left(\frac{d T}{d x}+\frac{d^{2} T}{d x^{2}} d x\right)
\end{aligned}
$$

Energy by convection $=\mathrm{h} \mathrm{A}(\mathrm{T}-\mathrm{T} \infty)=\mathrm{h} \mathrm{pdx}(\mathrm{T}-\mathrm{T} \infty)$
P is the perimeter $=2(\mathrm{z}+\mathrm{t}), \mathrm{A}=\mathrm{z} * \mathrm{t}$
When we combine the quantities, the energy balance yields

$$
\frac{d^{2} T}{d x^{2}}-\frac{h P}{k A}\left(T-T_{\infty}\right)=0
$$

Note: for cylinder
A $=\frac{\pi}{4} \mathrm{~d}^{2}$
$P=\pi d$

Let $\theta=(\mathrm{T}-\mathrm{T} \infty) \quad, \mathrm{m}=\sqrt{h p / k A}$
$\frac{d^{2} \theta}{d x^{2}}-\mathrm{m}^{2} \theta=0---------------2$
which has a general solution
$\theta=C 1 e^{-m x}+C 2 e^{m x}$ $\qquad$
Take 2 boundary condition
$\mathrm{T}=\mathrm{T}^{\circ}$ at $\mathrm{x}=0$
Let $\theta^{\circ}=\left(\mathrm{T}^{\circ}-\mathrm{T} \infty\right) \quad$ Applied B.C. 1 on equation 3
$\mathrm{T}^{\circ}-\mathrm{T} \infty=C_{1} e^{-m x}+C_{2} e^{m x}$ $\qquad$
$\mathrm{T}^{\circ}-\mathrm{T} \infty=C_{1}+C_{2}$
$\theta^{\circ}=C_{1}+C_{2}$ -4

The other boundary condition depends on the physical situation. Several cases may be considered:

CASE 1 The fin is very long, and the temperature at the end of the fin is essentially that of the surrounding fluid.

CASE 2 The end of the fin is insulated so that $d T / d x=0$ at $x=L$.
CASE 3 The fin is of finite length and loses heat by convection from its end.

| Case | Second B .C | $\frac{\theta}{\theta^{\circ}}$ |
| :--- | :--- | :---: |
| 1 | $\theta=0 \quad$ at $\mathrm{x}=\infty$ | $e^{-m x}$ |
| 2 | $\frac{d \theta}{d x}=0$ at $x=L$ | $\frac{\cosh [m(L-x)]}{\cosh (m L)}$ |
| 3 | $-\mathrm{kA} \frac{d \theta}{d x}=\mathrm{hpdx} \theta$ | $\frac{\cosh m(L-x)+(h / m k) \sinh m(L-x)}{\cosh m L+(h / m k) \sinh m L}$ |

Case $1 \mathrm{q}=\mathrm{kA} \mathrm{m} \theta^{\circ}=\sqrt{k A h p}\left(\mathrm{~T}^{\circ}-\mathrm{T} \infty\right)$
Case $2 \mathrm{q}=\mathrm{kA} \mathrm{m} \theta^{\circ} \tanh (\mathrm{mL})$
Case $3 \mathrm{q}=\mathrm{kA} \mathrm{m} \theta^{\circ} * \frac{\sinh m L+(h / m k) \cosh m L}{\cosh m L+(h / m k) \sinh m L}$
Notes:
1- For thin fin, $z \gg t, \quad p=2 z$
So $\mathrm{m}=\sqrt{2 h / k t}$
2- For cylindrical rod or pin
$\mathrm{P}=\pi \mathrm{d} \longrightarrow \mathrm{m}=\sqrt{2 h / k r}$
3- The solution in case 3 may be expressed same from of case 2 when the length is extended by one-half the thickness of the fin. In effect, lengthening of the fin by $t / 2$ is assumed to represent the same convection heat transfer as half the fin tip area placed on top and bottom of the fin. A corrected length $L c$ is then used in all the equations that apply for the case of the fin with an insulated tip

For rectangular fin $\mathrm{Lc}=\mathrm{L}+\frac{t}{2}$
[f a straight cylindrical rod extends from a wall, the corrected fin length is calculated

$$
\begin{array}{cl} 
& L_{c}=L+\frac{\pi d^{2} / 4}{\pi d}=L+d / 4 \\
\longrightarrow & \mathrm{Lc}=\mathrm{L}+\frac{r}{2}
\end{array}
$$

## Example:

A very long copper rod $\left(\mathrm{k}=372 \mathrm{w} / \mathrm{m}{ }^{\circ} \mathrm{C}\right) 2.5 \mathrm{~cm}$ in diameter has one end at $90{ }^{\circ} \mathrm{C}$..The rod is exposed to a fluid whose temperature is $40^{\circ} \mathrm{C}$. The heat transfer coefficient is $3.5 \mathrm{w} / \mathrm{m}^{2}{ }^{\circ} \mathrm{C}$. Calculate the heat loss from the rod.

Solution
$\mathbf{A}=\frac{\pi}{4} \mathrm{~d}^{2}=\frac{\pi}{4}(0.025)^{2}=4.91 * 10^{-4} \mathrm{~m}^{2}$
$\mathrm{P}=\pi \mathrm{d}=3.41 * 0.025=0.0785 \mathrm{~m}$
$\mathrm{q}=\mathrm{kA} \mathrm{m} \theta^{\circ}=\sqrt{k A h p}\left(\mathrm{~T}^{\circ}-\mathrm{T} \infty\right)=$

$$
\mathrm{k}=372
$$

$q=\sqrt{3.5 * 0.0785 * 372 * 4.91 * 10^{\wedge}-4} *(90-40)=11.2 \mathrm{~W}$

## Example:

An aluminum rectangular thin fin $\left[k=200 \mathrm{~W} / \mathrm{m} \cdot{ }^{\circ} \mathrm{C}\right]\left[\mathrm{A}=3^{*} 10^{-3}\right.$ $\left.\mathrm{m}^{2}\right] 3.0 \mathrm{~mm}$ thick and 7.5 cm long. The base is maintained at $300^{\circ} \mathrm{C}$, and the ambient temperature is $50^{\circ} \mathrm{C}$ with $h=10 \mathrm{~W} / \mathrm{m}^{2} \cdot{ }^{\circ} \mathrm{C}$. Calculate the heat loss from the fin.

Solution:
Case $3 \longrightarrow$ Lc $\longrightarrow$ Case 2
$\mathrm{L} c=\mathrm{L}+\frac{t}{2}=7.5+0.15=7.65 \mathrm{~cm}$
$\mathrm{m}=\sqrt{\frac{2 \mathrm{~h}}{\mathrm{kt}}}=\sqrt{\frac{2 * 10}{200 * 0.003}}=5.774$
$\mathrm{q}=\mathrm{kA} \mathrm{m} \theta^{\circ} \tanh (\mathrm{mLc})$
$\mathrm{q}=(5.774)(200)(3 \times 10-3)(300-50) \tanh [(5.774)(0.0765)]$
$=359 \mathrm{~W}$

## Example:

An aluminum cylindrical rod fin ( $\mathrm{k}=132 \mathrm{Btu} / \mathrm{h} . \mathrm{ft} .{ }^{\circ} \mathrm{F}$ ) having a diameter of 0.375 in and a length of 4 in is attached to a surface having $\mathrm{T}=200^{\circ} \mathrm{F}$.

The rod is exposed to ambient air $70 .{ }^{\circ} \mathrm{F}$ and heat transfer coefficient is 1.5 Btu / h. $\mathrm{ft}^{2} .{ }^{\circ} \mathrm{F}$. Determine temperature distribution and heat flux if a- Neglecting the heat transfer at the end.
b- Accounting the heat transfer at the end.
Solution:
a- Case 2

$$
\mathrm{m}=\sqrt{\frac{2 \boldsymbol{h}}{\boldsymbol{k r}}}=\sqrt{\frac{2 * 1.5}{132 *\left(\frac{0.1875}{12}\right)}}=1.206
$$

$\frac{\theta}{\theta^{\circ}}=\frac{T-T \infty}{T^{\circ}-T \infty}=\frac{\cosh [m(L-x)]}{\cosh m L}$
$\frac{T-70}{200-70}=\frac{\cosh \left[1.206\left(\frac{4}{12}-x\right)\right]}{\cosh \left(1.206 * \frac{4}{12}\right)}$
$\mathrm{T}=70+130 \frac{\cosh \left[1.206\left(\frac{4}{12}-x\right)\right]}{1.0819}$
$\mathrm{q}=\mathrm{kA} \mathrm{m} \theta^{\circ} \tanh (\mathrm{mL})$
$=132 * \frac{\pi}{\mathbf{4}}\left(\frac{\mathbf{0 . 3 7 5}}{\mathbf{1 2}}\right)^{2} * 1.206 *(200-70) \tanh \left(1.206 *\left(\frac{4}{12}\right)\right)$
$=6.055 \mathrm{~W}$
